

# INSTITUTE OF TECHNOLOGY AND MANAGEMENT SKILLS UNIVERSITY, KHARGHAR, NAVI MUMBAI

# **PYTHON PROGRAMMING LAB**

# Prepared by:

Name of Student: ATHARAV PATIL

Roll No: 31

Batch: 2023-27

**DEPARTMENT OF COMPUTER SCIENCE & ENGINEERING** 

Exp. No	List of Experiment
1	1. Write a program to compute Simple Interest.
	2. Write a program to perform arithmetic, Relational operators.
	3. Write a program to find whether a given no is even & odd.
	4. Write a program to print first n natural number & their sum.
	5. Write a program to determine whether the character entered is a Vowel or r
	6. Write a program to find whether given number is an Armstrong Number.
	7. Write a program using for loop to calculate factorial of a No.
	1.8 Write a program to print the following pattern
	i)
	*
	* *
	* * *
	* * * *
	* * * *
	ii)  1 22 333 4444 55555

	iii)
	*
	* * *
	* * * *
	* * * * * *
	* * * * * * * *
2	2.1 Write a program that define the list of defines the list of define countries the are in BRICS.
	2.2 Write a program to traverse a list in reverse order. 1.By using Reverse method. 2.By using slicing
	2.3 Write a program that scans the email address and forms a tuple of username and domain.
	2.4 Write a program to create a list of tuples from given list having number and add its cube in tuple. i/p: c= [2,3,4,5,6,7,8,9]
	2.5 Write a program to compare two dictionaries in Python? (By using == operator)
	2.6 Write a program that creates dictionary of cube of odd numbers in the range

	2.7 Write a program for various list slicing operation.			
	a= [10,20,30,40,50,60,70,80,90,100]			
	<ul> <li>i. Print Complete list</li> <li>ii. Print 4th element of list</li> <li>iii. Print list from0th to 4th index.</li> <li>iv. Print list -7th to 3rd element</li> <li>v. Appending an element to list.</li> <li>vi. Sorting the element of list.</li> <li>vii. Popping an element.</li> <li>viii. Removing Specified element.</li> <li>ix. Entering an element at specified index.</li> <li>x. Counting the occurrence of a specified element.</li> <li>xi. Extending list.</li> <li>xii. Reversing the list.</li> </ul>			
3	3.1 Write a program to extend a list in python by using given approach. i. By using + operator. ii. By using Append () iii. By using extend ()			
	3.2 Write a program to add two matrices.			
	3.3 Write a Python function that takes a list and returns a new list with distinct elements from the first list.			
	3.4 Write a program to Check whether a number is perfect or not.			
	3.5 Write a Python function that accepts a string and counts the number of upp and lower-case letters.  string_test= 'Today is My Best Day'			
4	4.1 Write a program to Create Employee Class & add methods to get employee details & print.			

	4.2 Write a program to take input as name, email & age from user using combination of keywords argument and positional arguments (*args and**kwa using function,
	4.3 Write a program to admit the students in the different Departments(pgdm/btech)and count the students. (Class, Object and Constructor).
	4.4 Write a program that has a class store which keeps the record of code and product display the menu of all product and prompt to enter the quantity of item required and finally generate the bill and display the total amount.
	4.5 Write a program to take input from user for addition of two numbers using (single inheritance).
	4.6 Write a program to create two base classes LU and ITM and one derived confidence (Multiple inheritance).
	4.7 Write a program to implement Multilevel inheritance, Grandfather→Father→Child to show property inheritance from grandfather the child.
	4.8 Write a program Design the Library catalogue system using inheritance base class (library item) and derived class (Book, DVD & Journal) Each derived class should have unique attribute and methods and system should support Chain and check out the system. (Using Inheritance and Method overriding)
5	5.1 Write a program to create my_module for addition of two numbers and imit in main script.
	5.2 Write a program to create the Bank Module to perform the operations such Check the Balance, withdraw and deposit the money in bank account and important module in main file.
	5.3 Write a program to create a package with name cars and add different mod (such as BMW, AUDI, NISSAN) having classes and functionality and import in main file cars.

6	6.1 Write a program to implement Multithreading. Printing "Hello" with one thread & printing "Hi" with another thread.
7.	7.1 Write a program to use 'whether API' and print temperature of any city, als print the sunrise and sunset times for the same humidity of that area.
	7.2 Write a program to use the 'API' of crypto currency.

Name of Student: ATHARAV PATIL

**Roll Number: 31** 

**Experiment No: 1.1** 

Title: Write a program to compute Simple Interest.

**Theory: Formula for Simple Interest=** 

Principal\*rate of interest\*time/100

Since principal, rate of interest, and time can be in decimal points, their datatype is float. Taking all these values from the user, and then printing the value of simple interest from these values.

#### Code:

```
a=float(input("Enter principal: "))
b=float(input("Enter rate of interest: "))
c=float(input("Enter time(in years): "))
print("Simple Interest:",(a*b*c)/100)
```

**Output:** (screenshot)

```
Enter principal: 12200
Enter rate of interest: 12

Enter time(in years): 2
Simple Interest: 2928.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

```
Enter principal: 12000
Enter rate of interest: 21
Enter time(in years): 2
Simple Interest: 5040.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

```
Enter principal: 50000
Enter rate of interest: 41
Enter time(in years): 5
Simple Interest: 102500.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

#### **Conclusion:**

Hence using the formula for simple interest, I have calculated it from the values given by the user and printed the result.

Title: Write a program to perform Arithmetic, Relational operators.

Theory: Arithmetic operators are those operators which perform mathematical arithmetic operations on the values or variables(eg- addition(+), subtraction(-), division(/), etc.) Relational operators are used to compare two or more values or variables(eg- less than(<), greater than(>), equal to(==) or not equal to(!=), etc.)

#### Code:

```
a=float(input("Enter first number: "))
b=float(input("Enter second number: "))
c=input("Select the operator: +,-,/,*,%,//,** ")
if c=="+":
   print("Sum:",a+b)
elif c=="-":
   print("Difference:",a-b)
elif c=="*":
   print("Multiplication:",a*b)
elif c=="/":
   print("Division:",a/b)
elif c=="%":
   print("Remainder:",a%b)
elif c=="//":
   print("Floor division:",a//b)
elif c=="**":
    print("Power:",a**b)
else:
    print("Invalid operator!")
if a>b:
   print(a,"is greater than",b)
elif a==b:
    print(a,"is equal to",b)
else:
   print(b,"is greater than",a)
```

# **Output:** (screenshot)

```
Enter first number: 20
Enter second number: 12
Select the operator: +,-,/,*,%,//,** *
Multiplication: 240.0
20.0 is greater than 12.0
```

```
Enter first number: 87
Enter second number: 54
Select the operator: +,-,/,*,%,//,** +
Sum: 141.0
87.0 is greater than 54.0
```

```
Enter first number: 45
Enter second number: 68
Select the operator: +,-,/,*,%,//,** %
Remainder: 45.0
68.0 is greater than 45.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence using the arithmetic, calculated the result of two values given by the user, andusing relational operators, printing the greater value given by the user.

Title: Write a program to find whether a given no is even & odd.

Theory: Even numbers are those numbers which are divisible by 2(eg- 2,4,6,8,10, so on) and odd numbers are those numbers which are not divisible by 2(eg- 1,3,5,7,9, so on).

To check whether a given number is odd or even, we need to check whether it is divisible by 2 using modulus operator(%).

#### Code:

```
a=int(input("Enter a number: "))
if a%2==0:
    print(a,"is an even number.")
else:
    print(a,"is odd number.")
```

**Output: (screenshot)** 

```
Enter a number: 90
90 is an even number.
atharavpatil@Atharavs—MacBook—Air prac.python %
```

Enter a number: 42
42 is an even number.

atnaravpatil@Atnaravs—MacBook— Enter a number: 23 23 is odd number.

Conclusion: Hence using the modulus operator(%), checked whether a given number is odd or even.

Title: Write a program to print first n natural number & their sum.

Theory: Natural numbers are numbers which start from 1 and go upto infinity. Using a for loop, print all the natural numbers and add them till the range given by the user.

#### Code:

```
a=int(input("Enter a number: "))
sum=0
if a<=0:
    print("Invalid number!")
else:
    for i in range(1,a+1):
        print(i)
        sum+=i
    print("Sum:",sum)</pre>
```

**Output: (screenshot)** 

```
atharavpatil@Atharavs-MacBook-Air prac.python % /usr/bin/p
Enter a number: 10
1
2
3
4
5
6
7
8
9
10
Sum: 55
o atharavpatil@Atharavs-MacBook-Air prac.python % []
```

```
Enter a number: 5

1

2

3

4

5

Sum: 15

atharavpatil@Atharavs-MacBook-Air prac.python %
```

```
Enter a number: 3

1

2

3

Sum: 6
atharavpatil@Atharavs-MacBook-Air prac.python %
```

#### **Conclusion:**

Hence using a for loop to iterate over each number from 1 to the range(given by the user which is inclusive), printed all the natural numbers and calculated their sum and printed it.

Title: Write a program to determine whether the character entered is a Vowel or not.

Theory: A character is a vowel if it is either A,E,I,O,U(be it lower or upper case). Else, it is not a vowel(consonant).

#### Code: a

```
a=["a","e","i","o","u"]
b=input("Enter a character: ")
if b.lower() in a:
    print(b,"is a vowel")
else:
    print(b,"is not a vowel")
```

**Output:** (screenshot)

<u>Enter</u> a character: a a is a vowel atharavpatil@Atharavs—MacBook—A

```
Enter a character: t
t is not a vowel
atharavpatil@Atharavs—MacBook—Air
```

```
Enter a character: e
e is a vowel
atharavpatil@Atharavs—MacBook—Air
```

#### **Conclusion:**

Hence using a membership operator(in) to check whether a user given character is inside the vowel list or not, and printing the appropriate message to the user.

Title: Write a program to find whether given number is an Armstrong Number. Theory: A positive number is called an Armstrong number of order n if abcd=a^n+b^n+c^n+d^n. Eg- 153(3 digits are there, therefore, order=3), therefore, 1^3+5^3+3^3=153. Therefore, 153 is an Armstrong number of order 3.

#### Code:

```
a=int(input("Enter a number: "))
b=len(str(a))
c=a
sum=0
while c!=0:
    d=c%10
    sum+=d**b
    c//=10
if sum==a:
    print(a,"is an armstrong number")
else:
    print(a,"is not an armstrong number")
```

**Output:** (screenshot)

```
Enter a number: 153
153 is an armstrong number
atharavpatil@Atharavs—MacBook—Air prac.python %
```

1)

Enter a number: 23 23 is not an armstrong number

2)

Enter a <a href="mailto:number">number</a>: 232 is not an armstrong number atharavpatil@Atharavs—MacBook—Air prac.

#### **Conclusion:**

Hence, calculating the order of the user given number(using len function), and adding the digits of the number raised to the power of the order(using while loop), and checking whether the sum is equal to the number(using relational operator ==) and printing the appropriate message(using if else statement).

Title: Write a program using for loop to calculate factorial of a number.

Theory: Factorial of a number is the product of all numbers from the number till . It is denoted by n!, where n is the number given by the user. Only positive numbers have a

factorial.

```
Eg- 5!=5*4*3*2*1=120
```

#### Code:

```
a=int(input("Enter a number: "))
fact=1
if a<0:
    print("Invalid number")
elif a==0 or a==1:
    print("Factorial:",1)
else:
    for i in range(1,a+1):
        fact*=i
    print("Factorial:",fact)</pre>
```

Output: (screenshot):-

```
Enter a number: 5
Factorial: 120
atharavpatil@Atharavs-MacBook-Air prac.python %
```

Enter a number: 3
Factorial: 6
atharavpatil@Atharavs-MacBook-Air prac

2)

Enter a number: 10
Factorial: 3628800

atharavpatil@Atharavs—MacBook—Air

#### **Conclusion:**

Hence, calculating the factorial of the user given number by first checking if it is a valid number (using if else statement), and using a for loop by calculating all the numbers from 1 to the number itself and printing it.

Title: Write a program to print the following pattern

#### Theory:

Using nested for loops to print ascending half pyramid pattern. One for loop for the rows and another for loop to print stars in each row. Number of stars in each row should be equal to the row they are in. Eg- In 4th row, there should be 4 stars, in 5th row, there should be 5 stars, etc.

#### Code:

```
for i in range(1,6):
    for j in range(i):
        print(" * ",end='')
    print("\n")
```

Output: (screenshot):-

```
atharavpatit@Atharavs=MacBook=Air prac.python % /usr/bin/py
*
    * *
    * * *
    * * *
    * * * *
    * * * *
    * atharavpatil@Atharavs=MacBook=Air prac.python %
```

Conclusion: H for loops.	Ience, printing a	a half pyramic	d ascending st	ar pattern usi	ng nested
Experiment N	lo: 1.8				

Title: Write a program to print the following pattern

ii)

1

2 2

333

4444

55555

Theory: Using nested for loops to print ascending half pyramid pattern. One for loop for the rows and another for loop to print numbers in each row. There should be n numbers and all numbers should have n value in nth row. Eg- In 4th row there should be 4 numbers and each one of them should be of the value 4.

Code:

```
ask = int(input("Enter the number of row : "))
for i in range(1,ask+1):
    print(i*f"{str(i)} ")
```

Output: (screenshot):-

```
■ atharavpatit@Atharavs—MacBook—Air prac
Enter the number of row : 5
1
2 2
3 3 3
4 4 4 4
5 5 5 5 5
○ atharavpatil@Atharavs—MacBook—Air prac
```

#### **Conclusion:**

Hence, printing a half pyramid ascending number pattern using nested for loops.

Title: Write a program to print the following pattern

Theory: Using nested for loops to print ascending pyramid pattern. One for loop for the rows and another for loop to print stars in each row. There should be 2n-1 stars in nth row.

Eg- In 4th row there should be 2(4)-1=7 stars, in 5th row there should be 2(5)-1=9 stars.

Code:

```
for i in range(1,6):
    for j in range(6,i,-1): #pyramid pattern ascending
        print(" ",end='')
    for k in range(2*i-1):
        print("*",end='')
    print()
```

### **Output(Screenshot):-**

```
*
***
****

*****

******

********

atharavpatil@Atharavs—MacBook—Air prac.python %
```

Conclusion: Hence, printing a half pyramid ascending number pattern using				
nested for loops.				

Title: Write a program that define the list of defines the list of define countries that are in BRICS.

Theory: BRICS countries= Brazil, Russia, India, China, South Africa.

Using a membership operator(in), can check whether country given by user is a BRICS member or not. Can use in operator to check whether the value of variable is inside BRICS list or not.

#### Code:

```
brics=["brazil","russia","india","china","south africa"]
a=input("Enter a country: ")
if a.lower() in brics:
    print(a,"is a member of BRICS")
else:
    print(a,"is not a member of BRICS")
```

Output(Screenshot):-

```
Enter a country: India
India is a member of BRICS
atharavpatil@Atharavs—MacBook—Air prac.p
```

2)

```
Enter a country: dubai
dubai is not a member of BRICS
atharavpatil@Atharavs—MacBook—Air prac.python %
```

Enter a country: brazil brazil is a member of BRICS atharavpatil@Atharavs—MacBook—Air prac.python

Conclusion: Hence, using a membership operator(in), check user given country is in BRICS or not and printing the appropriate message using if else statement.

Title: Write a program to traverse a list in reverse order.

- 1.By using Reverse method.
- 2.By using slicing

Theory: 1. By using predefined function reverse(), we can reverse a list and print it.

2. By using index slicing, we can print the list in reverse using step size as -1.

#### Code:

1.

```
a=[]
n=int(input("Enter number of elements: "))
for i in range(n):
   b=int(input("Enter an element: "))
    a.append(b)
print(a)
a.reverse()
print("Reversed list:",a)
2.
a=[]
n=int(input("Enter number of elements: "))
for i in range(n):
    b=int(input("Enter an element: "))
    a.append(b)
print(a)
print("Reversed list:",a[::-1])
```

# Output(Screenshot):-

```
Enter number of elements: 3
Enter an element: 23
Enter an element: 45
Enter an element: 67
[23, 45, 67]
Reversed list: [67, 45, 23]
Enter number of elements: 2
Enter an element: 34
Enter an element: 56
[34, 56]
Reversed list: [56, 34]
atharavpatil@Atharavs-MacBook-Air prac.python s
```

Conclusion: Hence, traversing the index in reverse order using index slicing and predefined function reverse().

Title: Write a program that scans the email address and forms a tuple of username and domain.

#### **Theory:**

Using split() function with @ as a parameter to split the email address given by user and store it in a tuple. Then print the first element of the tuple as username and the second element from the same tuple as domain.

#### **Code:**

```
a=input("Enter your email address: ")
if "@" in a:
    b=(a.split("@"))
    c=(b[0],b[1])
    print("User name:",c[0])
    print("Domain:",c[1])
else:
    print("Wrong email address entered")
```

# **Output(Screenshot):**

```
Enter your email address: atharav01@gmail.com
User name: atharav01
Domain: gmail.com
atharavpatil@Atharavs—MacBook—Air prac.python %
```

**Test Case: Any two (screenshot)** 

1)

```
Enter your email address: atharav
Wrong email address entered
atharavpatil@Atharavs—MacBook—Air prac.python
```

Enter your email address: 2023.atharav@isu.ac.in User name: 2023.atharav

Domain: isu.ac.in

atharavpatil@Atharavs-MacBook-Air prac.python %

# **Conclusion:**

Hence, using split() function to split the email address in username and domain and printing them after storing them in a tuple.

Title: Write a program to create a list of tuples from given list having number and add its cube in tuple.

$$i/p$$
: c= [2,3,4,5,6,7,8,9]

Theory: Using list comprehension, make another list with tuples as its elements. Each tuple would have the number from original list and it's cube using arithmetic operator(\*\*).

#### Code:

```
c= [2,3,4,5,6,7,8,9]
a=[(num,num**3)for num in c]
print(a)
```

# **Output(Screenshot):**

```
    atharavpatil@Atharavs-MacBook-Air prac.python % /usr/bin/python3 /Users/atharavpa [(2, 8), (3, 27), (4, 64), (5, 125), (6, 216), (7, 343), (8, 512), (9, 729)]
    atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, using list comprehension to make a list of tuples containing the values and their cube using \*\* operator from the original list.

Title: 2.5 Write a program to compare two dictionaries in Python

```
(By using == operator)
```

Theory: Dictionary is a datatype in Python which stores information as key-value pairs, where keys are unique and are used to distinguish between values. Using relational

operator(==) to check whether two dictionaries have same key-value pairs or not.

#### Code:

```
a={1:1,2:"a",3:23,4:52}
b={1:1,2:"a",3:23,4:52}
if a==b:
    print("Both the dictionaries are equal")
else:
    print("Both the dictionaries are not equal")
```

#### **Output(Screenshot):**

```
    atharavpatil@Atharavs-MacBook-Air prac.python % /usr/bin/pyt
    Both the dictionaries are equal
    atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, using == operator to check whether two dictionaries have same key-value pairsor not and printing appropriate messages using if else statements.

Title: Write a program that creates dictionary of cube of odd numbers in the range.

Theory: Using for loop to iterate over every number from 1 till range given by user and using if statement to check whether a number is odd or even using modulus operator(%) and making the number as key and its cube as a value, and printing the dictionary in the end.

#### Code:

```
a=int(input("Enter range: "))
b={}
for i in range(1,a):
    if i%2!=0:
        b[i]=i**3
print(b)
```

# **Output(Screenshot):**

```
atharavpatit@Atharavs—MacBook—Air prac.python %
Enter range: 4
{1: 1, 3: 27}
atharavpatil@Atharavs—MacBook—Air prac.python %
```

1)

```
Enter range: 8
{1: 1, 3: 27, 5: 125, 7: 343}
atharavpatil@Atharavs-MacBook-Air prac.python
```

2)

```
Enter range: 15
{1: 1, 3: 27, 5: 125, 7: 343, 9: 729, 11: 1331, 13: 2197}
atharavpatil@Atharavs-MacBook-Air prac.python %
```

#### **Conclusion:**

Hence, using for loop and if statement to create a dictionary of odd numbers as keys and their cube as values and printing the dictionary.

Title: Write a program for various list slicing operation.

a = [10,20,30,40,50,60,70,80,90,100]

- i. Print Complete list
- ii. Print 4th element of list
- iii. Print list from0th to 4th index.
- iv. Print list -7th to 3rd element
- v. Appending an element to list.
- vi. Sorting the element of list.
- vii. Popping an element.
- viii. Removing Specified element.
- ix. Entering an element at specified index.
- x. Counting the occurrence of a specified element.
- xi. Extending list.
- xii. Reversing the list.

Theory: Using index slicing to print specific elements, predefined functions such as append() to add an element in the list, sort() to sort the list in ascending or descending order, pop() to remove and element in the list, insert() to add an element in the list at a specific index, remove() to remove a specific element from the list, for loop to check the occurrence of an element, extend() to add multiple elements in the list, reverse() to reverse the list.

```
Code:
```

```
a= [10,20,30,40,50,60,70,80,90,100]
print(a)
print(a[3]) #Print 4th element of list
print(a[0:4]) #Print list from0th to 4th index.
print(a[-7:4]) #Print list -7th to 3rd element
a.append(110) #Appending an element to list.
print(a)
a.sort() #Sorting the element of list.
print(a)
a.sort(reverse=True) #Sorting the element of list in descending
order.
print(a)
a.pop() #Popping an element.
print(a)
b=int(input("Enter element to remove: "))
if b in a:
    a.remove(b) #Removing Specified element.
   print(a)
else:
   print("Invalid element")
b=int(input("Enter element to add: "))
c=int(input("Enter index where to insert: "))
a.insert(c,b) #Entering an element at specified index.
print(a)
b=int(input("Enter element to count: "))
count=0
for i in a:
    if i==b:
        count+=1 #Counting the occurrence of a specified element.
print("Count of element:",count)
c=int(input("Enter number of elements: "))
d=[]
for i in range(c):
   b=int(input("Enter element: "))
   d.append(b)
a.extend(d) #Extending list.
print(a)
```

```
a.reverse() #Reversing the list.
print(a)
Output(Screenshot):
```

```
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100]
40
[10, 20, 30, 40]
[40]
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110]
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110]
[110, 100, 90, 80, 70, 60, 50, 40, 30, 20, 10]
[110, 100, 90, 80, 70, 60, 50, 40, 30, 20]
Enter element to remove: 20
[110, 100, 90, 80, 70, 60, 50, 40, 30]
Enter element to add:
```

# Test Case: Any two (screenshot):-

```
atharavpatil@Atharavs-MacBook-Air prac.python % /usr/bin/py-
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100]
40
[10, 20, 30, 40]
[40]
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110]
[10, 20, 30, 40, 50, 60, 70, 80, 90, 100, 110]
[110, 100, 90, 80, 70, 60, 50, 40, 30, 20, 10]
[110, 100, 90, 80, 70, 60, 50, 40, 30, 20]
Enter element to remove: 100
[110, 90, 80, 70, 60, 50, 40, 30, 20]
Enter element to add: 120
Enter index where to insert: 5
[110, 90, 80, 70, 60, 120, 50, 40, 30, 20]
Enter element to count: 20
Count of element: 1
```

Conclusion: Hence, using for loop, slicing, and various predefined list functions to add, remove, sort and reverse a list.

Title: Write a program to extend a list in python by using given approach.

- i. By using + operator.
- ii. By using Append ()
- iii. By using extend ()

### Theory:

+ operator is used to add a list to another list. Append() is used to add an element at

the end of the list. Extend() is used to add multiple elements at the end of the list.

```
a=[1,2,3,4,5]
b=int(input("Enter number of elements: "))
for i in range(b):
   d=int(input("Enter element: "))
    c.append(d)
a+=c #using + operator
print(a)
b=int(input("Enter element: "))
a.append(b) #using append()
print(a)
c=[]
b=int(input("Enter number of elements: "))
for i in range(b):
    d=int(input("Enter element: "))
    c.append(d)
a.extend(c) #using extend()
print(a)
```

### **Output(Screenshot):**

```
Enter number of elements: 2
Enter element: 23
Enter element: 45
[1, 2, 3, 4, 5, 23, 45]
```

Test Case: Any two (screenshot):-

1)

```
Enter number of elements: 2
Enter element: 23
Enter element: 45
[1, 2, 3, 4, 5, 23, 45]
Enter element:
```

2)

```
Enter number of elements: 2
Enter element: 23
Enter element: 45
[1, 2, 3, 4, 5, 23, 45]
Enter element: 78
[1, 2, 3, 4, 5, 23, 45, 78]
Enter number of elements: 98
```

Conclusion: Hence, using for loop and if statement to create a dictionary of odd numbers as keys and their cube as values and printing the dictionary.

Title: Write a program to add two matrices.

Theory: A matrix is a nested list in Python(a list of lists). It consists of two lists which have three lists inside each of them. Using nested for loop, one for each of the two lists, add elements from the two matrices and store the sum in another matrix of same dimension and print it.

#### Code:

```
a=[[2,5,4],[1,3,9],[7,6,2]]
b=[[1,8,5],[7,3,6],[4,0,9]]
c=[[0,0,0],[0,0,0],[0,0,0]]
for i in range(len(a)):
    for j in range(len(b)):
        c[i][j]=a[i][j]+b[i][j]
print(c)
```

**Output(Screenshot):-+ Test Case: (screenshot)** 

```
atharavpatil@Atharavs—MacBook—Air prac.python % /usr/bi
[[3, 13, 9], [8, 6, 15], [11, 6, 11]]
```

Conclusion: Hence, using nested for loop, add the elements of two nested lists and store the sum in another nested list

Title: Write a Python function that takes a list and returns a new list with distinct elements from the first list.

Theory: Making a user defined function distin() taking a user list as a parameter and then making an empty list and using a for loop to iterate through the user list and using membership operator(in) to check whether the element is present in the empty list too. If it is not present, append it in the list and check the next element for the same.

#### Code:

```
def distin(a):
    b=[]
    for i in a:
        if i not in b:
            b.append(i)
    print(b)
a=[]
while True:
    c=int(input("Enter a number(0 to exit): "))
    if c == 0:
        break
    else:
        a.append(c)
print(a)
print("Distinct list:")
distin(a)
```

# Output(Screenshot):-

```
Enter a number(0 to exit): 20
Enter a number(0 to exit): 12
Enter a number(0 to exit): 12
Enter a number(0 to exit): 34
Enter a number(0 to exit): 56
Enter a number(0 to exit): 21
Enter a number(0 to exit): 23
Enter a number(0 to exit): 12
Enter a number(0 to exit): 0
[20, 12, 12, 34, 56, 21, 23, 12]
Distinct list:
[20, 12, 34, 56, 21, 23]
atharavpatil@Atharavs-MacBook-Air prac.python %
```

### **Test Case: (screenshot)**

```
Enter a number(0 to exit): 20
Enter a number(0 to exit): 32
Enter a number(0 to exit): 12
Enter a number(0 to exit): 4
Enter a number(0 to exit): 0
[20, 32, 12, 4]
Distinct list:
[20, 32, 12, 4]
Datharavpatil@Atharavs—MacBook—Air prac.python %
```

Conclusion: Hence, by making a function, using nested for loop to check whether each element in the list is only present once and appending it to another list and then printing the other list at the end.

Title: Write a program to Check whether a number is perfect or not.

Theory: A number is a perfect number if the sum of its divisors(excluding the number itself) is equal to the number itself. Eg- 6 is a perfect number as divisors of 6 are 1,2,3. Sum- 1+2+3=6 which is equal to the number itself.

#### Code:

```
def perfect(a):
    sum = 0
    for i in range(1, a):
        if a % i == 0:
            sum += i
    if sum == a:
        print(a, "is a perfect number")
    else:
        print(a, "is not a perfect number")
a = int(input("Enter a number: "))
perfect(a)
```

### **Output(Screenshot):**

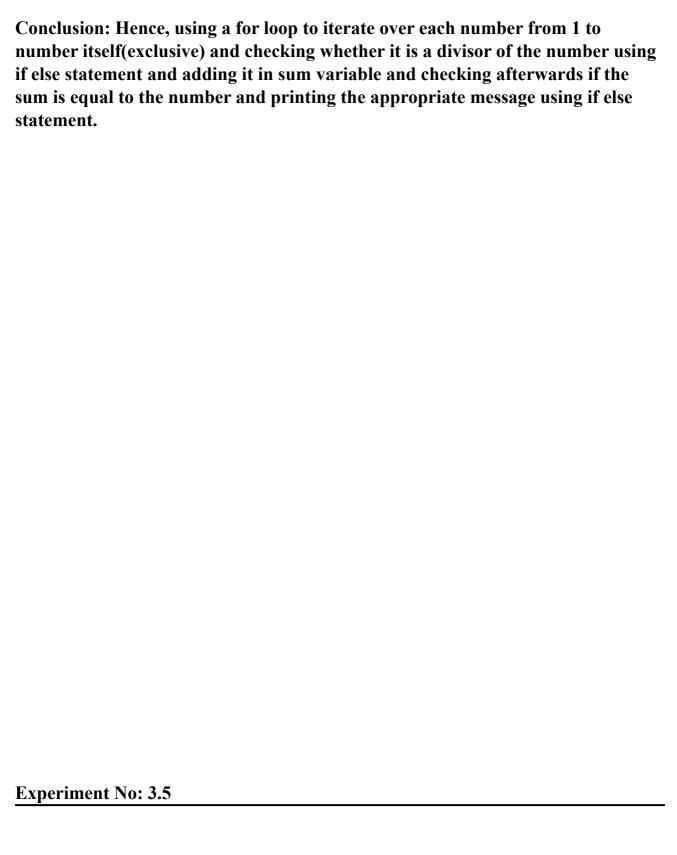

```
Enter a number: 28
28 is a perfect number
30 atharavpatil@Atharavs—MacBook—Air prac.python %
```

**Test Case: Any two (screenshot)** 

```
Enter a number: 12

12 is not a perfect number
```

```
Enter a number: 34
34 is not a perfect number
```

Title: Write a Python function that accepts a string and counts the number of upper-case and lower-case letters.

Theory: Using a for loop to iterate each character in the string and if elif statement and predefined functions isupper() and islower() to check whether a character is lowercase or uppercase and incrementing the value of the respective uppercase or lowercase counter by 1.

#### Code:

```
a=input("Enter a string: ")
ucount=0
lcount=0
for i in a:
    if i.islower():
        lcount+=1
    elif i.isupper():
        ucount+=1
print(a)
print("Number of lower case letters:",lcount)
print("Number of upper case letters:",ucount)
```

# **Output(Screenshot):**

```
Enter a string: Atharav Patil
Atharav Patil
Number of lower case letters: 10
Number of upper case letters: 2
atharavpatil@Atharavs—MacBook—Air prac.python %
```

**Test Case: (screenshot)** 

```
Enter a string: humpty
humpty
Number of lower case letters: 6
Number of upper case letters: 0
atharavpatil@Atharavs—MacBook—Air prac.python %
```

Conclusion: Hence, using a for loop to iterate over each character in the string and using isupper() and islower() to check the characters and increment the counter variables value by 1 using if elif statement

Title: Write a program to Create Employee Class & add methods to get employee details & print.

Theory: A class is a blueprint for objects. It contains attributes and methods which the objects can access and use. An object is an instance of a class. Each class has its own copy of attributes and share the methods of the class.

```
class Employee:
      name=""
      age=0
      salary=0
     post="i
    def setData(self):
         name=input("Enter employee name: ")
         self. name=name
         age=int(input("Enter age of employee: "))
         self. age=age
         salary=float(input("Enter salary of employee: "))
         self.__salary=salary
         post=input("Enter post of employee: ")
         self.__post=post
    def getData(self):
         print("\nEmployee Data:")
         print("Name:", self.__name)
print("Age:", self.__age)
print("Salary:", self.__salary)
         print("Post:", self. post)
a=Employee()
a.setData()
a.getData(
```

### **Output(Screenshot):-**

```
Enter employee name: atharav
Enter age of employee: 12
Enter salary of employee: 200000
Enter post of employee: manager

Employee Data:
Name: atharav
Age: 12
Salary: 200000.0
Post: manager
atharavpatil@Atharavs—MacBook—Air prac.python %
```

### Test Case: (screenshot):-

```
Enter employee name: ROMIL
Enter age of employee: 40
Enter salary of employee: 90000000
Enter post of employee: postman

Employee Data:
Name: ROMIL
Age: 40
Salary: 90000000.0
Post: postman
```

Conclusion: Hence, using get and set data functions to take values from the user and then assigning the attributes of the object these values and printing them to the user.

Title: Write a program to take input as name, email & age from user using combination of keywords argument and positional arguments (\*args and\*\*kwargs) using function.

Theory: While defining a function, we use \*args and \*\*kwargs as parameters when we don't know how many arguments the user will pass during function call. \*args will take a tuple of positional arguments as parameter and work on it. \*\*kwargs will take a dictionary of keyword arguments as parameter and assign the keys to keywords in arguments and the values as the values passed by the user in the arguments.

#### Code:

```
def kbfunction(*args, **kwargs):
    for i in args:
        print("Name:",i)
    for i in kwargs:
        print(i,":",kwargs[i])
b=input("Enter your name: ")
c=int(input("Enter your age: "))
a=input("Enter your email: ")
kbfunction(b,age=c,email=a)
```

# **Output(Screenshot):**

```
Enter your name: Atharav
Enter your age: 20
Enter your email: atharav01@gmail.com
Name: Atharav
age: 20
email: atharav01@gmail.com
atharavpatil@Atharavs-MacBook-Air prac.python % /usi
```

### Test Case: (screenshot):-

```
    atharavpatil@Atharavs-MacBook-Air prac.python % /usr/bin/pyth Enter your name: jadhav Enter your age: 21
        Enter your email: jadhav23@gmail.com
        Name: jadhav age: 21
        email: jadhav23@gmail.com
    atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, using dynamic argument passing(\*args and \*\*kwargs) to take multiple arguments from the user in a combination of positional and keyword arguments and printing them using a user defined function.

# **Experiment No: 4.3**

Title: Write a program to admit the students in the different Departments(pgdm/btech) and count the students. (Class, Object and Constructor).

Theory: A constructor is automatically called when an object is created for a class. It is defined by \_\_init\_\_(self). It is used to initialise all the attributes of a class and self is a pointer which is used to tell the program to make changes only in a particular object and not access data or modify other objects.

```
class ITM:
    count=0
    bcount=0
    pcount=0
    def init (self):
        self.count=0
        self.bcount=0
        self.pcount=0
    def getData(self):
        a=input("Enter student name:" )
        b=int(input("Enter age: "))
        c=input("Enter address: ")
        d=int(input("Select department(1/2):\n1.BTECH\n2.PGDM\n"))
        while not(d==1 or d==2):
            print("Invalid choice\n")
            d=int(input("Select department(1/2):
\n1.BTECH\n2.PGDM\n"))
        if d==1:
            self.dep="BTECH"
            ITM.bcount+=1
        elif d==2:
            self.dep="PGDM"
            ITM.pcount+=1
        self.name=a
        self.age=b
        self.address=c
        ITM.count+=1
    def setData(self):
        print("Student Details:\n")
        print("Name:", self.name)
        print("\nAge:",self.age)
        print("\nAddress:",self.address)
        print("\nDepartment:",self.dep)
a=int(input("Welcome to ITM. Press:\n1.Enter Student Data\n2.Number
of admissions\n3.Display students data\n4.Exit\n"))
objs=list()
while a!=4:
   if a==1:
```

```
d=int(input("Enter number of students: "))
       for i in range(d):
            objs.append(ITM())
        for i in range(d):
            objs[i].getData()
       a=int(input("\nPress\n1.Enter another data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
   elif a==2:
       b=int(input("Press\n1.BTECH admissions\n2.PGDM
admissions\n"))
       while not (b==1 or b==2):
            print("Invalid choice\n")
            b=int(input("Press\n1.BTECH admissions\n2.PGDM
admissions\n"))
        if b==1:
            print("Admissions of BTECH Done:",ITM.bcount)
           print("Total admissions:",ITM.count)
            a=int(input("\nPress\n1.Enter student data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
       elif b==2:
            print("Admissions of PGDM Done:",ITM.pcount)
           print("Total admissions:",ITM.count)
           a=int(input("\nPress\n1.Enter student data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
   elif a==3:
       b=int(input("\nPress\n1.For BTECH students data\n2.For PGDM
students data\n"))
       if b==1:
            for i in range(d):
                if objs[i].dep=="BTECH":
                    objs[i].setData()
            a=int(input("\nPress\n1.Enter student data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
       elif b==2:
            for i in range(d):
                if objs[i].dep=="PGDM":
                    objs[i].setData()
            a=int(input("\nPress\n1.Enter student data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
       else:
            print("Invalid choice")
            a=int(input("\nPress\n1.Enter student data\n2.Number of
admissions\n3.Display student details\n4.Exit\n"))
   elif a==4:
       break
   else:
        print("Invalid choice")
       break
```

### **Output(Screenshot):-**

Admissions of BTECH Done: 1
Total admissions: 1
```

Conclusion: Hence, using constructors and get and set functions and using while loop to print a menu to the user and call functions as per the user's need and making a list of objects to store information of multiple students of different branches.

Title: Write a program that has a class store which keeps the record of code and price of product display the menu of all product and prompt to enter the quantity of each item required and finally generate the bill and display the total amount.

Theory: Using constructor to print a menu of items to the user and getting quantity of the product and printing the bill with total amount at the end.

```
class Store:
     itemCode=0
     price=0
     total=0
   product=[]
   quantity=[]
   price=[]
   def init (self):
       print("Welcome to ABC Store!")
       while True:
           a=int(input("Select a product:
if a==1:
               self. itemCode=1
              self.__price=50
           elif a==2:
              self.__itemCode=2
               self.
                     price=100
           elif a==3:
              self.__itemCode=3
               self.__price=200
           elif a==4:
              self.__itemCode=4
               self.__price=150
           elif a==5:
              self. itemCode=5
           self.__price=500
print("Product:",c[a-1],"\nPrice:",self.__price)
           self.product.append(c[a-1])
           self.price.append(self.__price)
           b=int(input("Enter the quantity: "))
```

**Output(Screenshot):** + Test Case: (screenshot)

```

                 50
                                 2
Book
                 500
Total: 2600
atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, using constructor, printing a bill with total amount at the end.

Title: Write a program to take input from user for addition of two numbers using (single inheritance).

### **Theory:**

Single inheritance is when there is a single parent class and a single child class which inherits the attributes and methods of the parent class. It reduces lines of code as instead of writing the same attributes and methods again in a new class, we can simply inherit them.

#### Code:

```
class Addition:
    def add(a,b):
        print("Sum:",a+b)

class Numbers(Addition):
    def getNumbers(self):
        c=float(input("Enter a number: "))
        d=float(input("Enter another number: "))
        Addition.add(c,d)

e=Numbers()
e.getNumbers()
```

# **Output(Screenshot):**

```
Enter a number: 23
Enter another number: 12
Sum: 35.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

### **Test Case: (screenshot)**

```
Enter a number: 34
Enter another number: 45
Sum: 79.0
atharavpatil@Atharavs—MacBook—Air prac.python %
```

Conclusion: Hence, using single inheritance to take values from the user from method of child class and adding and printing the sum from method of parent class.

Title: Write a program to create two base classes LU and ITM and one derived class. (Multiple inheritance).

Theory: Multiple inheritance is when a single child class inherits methods and attributes from multiple parent classes.

```
class LU:
     subjects=["AI/ML","AR/VR","Cloud Computing","Full Stack
Developer"l
    teachers=["Sai Sir","Swapnil Sir","ABC","XYZ"]
duration=["60 days","30 days","50 days","55 days"]
class ITM:
    subjects=["Hotel management","BTECH CSE","Design","Business"]
teachers=["abc","Sumit sir","xyz","qwer"]
duration=["90 days","120 days","60 days","30 days"]
class Btech(LU,ITM):
     print("LetsUpgrade courses are:\n")
     a=LU.subjects
     i=1
     for i in range(len(a)):
print(j,LU.subjects[i],"by",LU.teachers[i],"for",LU.duration[i])
     c = [1]
    d=int(input("How many subjects you want to select: "))
     if d>4:
          print("Invalid number of subjects")
     else:
          for i in range(d):
              e=int(input("Select your interested course: "))
               c.append(e)
     print("\nITM courses are:\n")
     j=1
     b=ITM.subjects
     for i in range(len(b)):
```

```
print(j,ITM.subjects[i],"by",ITM.teachers[i],"for",ITM.duration[i])
        j+=1
    f=[]
    d=int(input("How many subjects you want to select: "))
    if d>4:
        print("Invalid number of subjects")
    else:
        for i in range(d):
            e=int(input("Select your interested course: "))
            f.append(e)
    i=1
    print("\nYour selected courses are:\n")
    for i in c:
print(j,LU.subjects[i-1],"by",LU.teachers[i-1],"for",LU.duration[i-
1])
        i += 1
    for i in f:
print(j,ITM.subjects[i-1],"by",ITM.teachers[i-1],"for",ITM.duration
[i-1]
        j+=1
obi=Btech()
```

7 BTECH CSE by Sumit sir for 120 days
8 BTECH CSE by Sumit sir for 120 days
8 BTECH CSE by Sumit sir for 120 packed.
```

#### **Conclusion:**

Hence, using multiple inheritance to show courses from multiple classes(LU and ITM) and print courses and their details which the user chooses.

Title: Write a program to implement Multilevel inheritance, Grandfather-

>Father->Child to show property inheritance from grandfather to child.

Theory: Multilevel inheritance is when there is a parent class which has a child class which in turn has a child class of its own. The last child class inherits all the methods and attributes from its parent class as well as from the grandfather class.

#### Code:

```
class Grandfather:
    def init (self):
        self.name="ABC"
        self.inherit=10000
        self.purchase=1000
class Father(Grandfather):
    def __init__(self):
    super().__init__()
        self.name=" XYZ "+self.name
        self.inherit=self.inherit
        self.purchase=10000+self.purchase
class Child(Father):
    def __init__(self,name):
    super().__init__()
        self.name=name+self.name
        self.inherit=self.inherit
        self.purchase=self.purchase
        print("Hello", self.name)
        print("Inherited property: Rs", self.inherit)
        print("Purchased property: Rs", self.purchase)
        print("Total property:",self.inherit+self.purchase)
a=input("Enter your name: "
obi=Child(a)
```

### Output(Screenshot):-

```
Enter your name: Atharav
Hello Atharav XYZ ABC
Inherited property: Rs 10000
Purchased property: Rs 11000
Total property: 21000
atharavpatil@Atharavs-MacBook-Air prac.python %
```

# **Conclusion:**

Hence, using multilevel inheritance to take name from the user and calculate inherited and purchased property from grandfather and father for the child and their full name using methods and attributes from the grandfather and father class.

Title: Write a program Design the Library catalogue system using inheritance take base class (library item) and derived class (Book, DVD & Journal) Each derived class should have unique attribute and methods and system should support Check in and check out the system. (Using Inheritance and Method overriding)

Theory: Method overriding is when there is a method of same name in both base class and derived class and when an object is created of derived class and method is called, derived class object is called and base class method is overridden.

```
class Library_item:
        _bookCount=0
        dvdCount=0
         journalCount=0
        quantity=[]
        cart=[]
class Book(Library_item):
    def init_(self):
        super().__init__()
        def check out book(self):
             d=int(input("How many books you want to select?: "))
             if d>4:
                 print("Invalid choice")
             else:
                 for i in range(d):
                     c=int(input("Select a book: "))
                     f=int(input("Enter quantity: "))
                     Library item.quantity.append(f)
                     self.cart.append(a[c-1])
                     Library_item._bookCount+=1
                 print(self.cart)
                 print("Books selected:",Library_item._bookCount)
a=["C programming by Ritchie-Cunningham","C++ by
Balaguruswamy","R.D. Sharma","Class 12 CS by NCERT"]
        b=1
        for i in range(len(a)):
             print(b,a[i])
```

```
b += 1
        check out book(self)
class Dvd(Library_item):
    def __init__(self):
    super().__init__()
        def check out dvd(self):
            d=int(input("How many DVD's you want to select?: "))
            for i in range(d):
                 if d>4:
                     print("Invalid choice")
                else:
                     c=int(input("Select a DVD: "))
                     f=int(input("Enter quantity: "))
                     Library_item.quantity.append(f)
                     self.cart.append(a[c-1])
                     Library_item._dvdCount+=1
            print(self.cart)
            print("DVDs selected:",Library_item._dvdCount)
        a=["Avengers","Justice League","Conjuring","ABC"]
        b=1
        for i in range(len(a)):
            print(b,a[i])
            b += 1
        check_out_dvd(self)
class Journal(Library_item):
    def __init__(self):
        super().__init__()
def check_out_journal(self):
            d=int(input("How many Journal you want to select?: "))
            if d>4:
                 print("Invalid choice")
            else:
                 for i in range(d):
                     c=int(input("Select a journal: "))
                     f=int(input("Enter quantity: "))
                     Library_item.quantity.append(f)
                     self.cart.append(a[c-1])
                     Library_item._journalCount+=1
                print(self.cart)
                print("Journals
selected:",Library_item._journalCount)
        a=["A Journal","XYZ Journal","ABC Journal","QWERTY
Journal"l
        b=1
        for i in range(len(a)):
            print(b,a[i])
            b += 1
        check_out_journal(self)
class Checkout(Library item):
```

```
def __init__(self):
        super(). init ()
        print("\nCheckout")
        j=1
        for i in range(len(self.cart)):
            print(j,self.cart[i],"-",self.quantity[i])
            j+=1
        print("\nBooks selected:",self._bookCount)
        print("Journals selected:",self._journalCount)
        print("DVDs selected:",self. dvdCount)
print("Total:",self._bookCount+self._journalCount+self._dvdCount)
objs=list()
print("Welcome to ABC Library!")
for i in range(100):
    a=int(input("\nPress:\n1.Book Catalogue\n2.DVD
Catalogue\n3.Journal Catalogue\n4.Checkout\n5.Exit\n"))
    if a==1:
        objs.append(Book())
    elif a==2:
        objs.append(Dvd())
    elif a==3:
        objs.append(Journal())
    elif a==4:
        objs.append(Checkout())
    elif a==5:
        print("Thank You!")
        break
    else:
        print("Invalid choice")
        Break
```

#### **Output(Screenshot):**

```
Welcome to ABC Library!
Press:
1.Book Catalogue

2 A Journal - 2
3 ABC Journal - 2

Books selected: 0
Journals selected: 2
DVDs selected: 1
```

Conclusion: Hence, using single inheritance and method overriding, made a library catalogue system having checkout system for books, movies, and journals.

Title: Write a program to create my\_module for addition of two numbers and import it in main script.

Theory: Module is a collection of functions. Its functions can be used in another program by importing the module.

#### Code:

```
import my_module
a=my_module.Addition()
b=float(input("Enter a number: "))
c=float(input("Enter another number: "))
a.add(b,c)
```

### **Output(Screenshot):**

```
atharavpatil@Atharavs-MacBook-Air prac.
Enter a number: 3
Enter another number: 4
7.0
atharavpatil@Atharavs-MacBook-Air prac.
```

### **Test Case: (screenshot)**

```
Enter a number: 5
Enter another number: 5
10.0
atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, creating a module for addition of two values given by the user and printing it by importing the module in main program.

# **Experiment No: 5.2**

Title: Write a program to create the Bank Module to perform the operations such as check the Balance, withdraw and deposit the money in bank account and import the module in main file.

Theory:

```
from bank_module import ATM
b=ATM()
while True:
    a=int(input("Press 1 to deposit\nPress 2 to withdraw\nPress 3
to check balance\nPress 4 to Exit\n"))
    if a==1:
        b.deposit()
    elif a==2:
        b.withdraw()
    elif a==3:
        b.check()
    elif a==4:
        print("Thank You")
        break
    else:
        print("Invalid choice\n")
```

### **Output(Screenshot):**

```
Welcome to ABC Bank

Press 4 to Exit
Balance: Rs 9000143800.0
Your Account Number XXXXXXXX456354
Press 1 to deposit
Press 2 to withdraw
Press 3 to check balance
Press 4 to Exit
Thank You
atharavpatil@Atharavs-MacBook-Air prac.python %
```

Conclusion: Hence, creating a module for bank ATM with functions for deposit, withdraw, and checking bank balance and asking the user for deposit, withdraw or check bank balance and calling the user specified function using while loop.

### **Experiment No: 5.3**

Title: Write a program to create a package with name cars and add different modules (such as BMW, AUDI, NISSAN) having classes and functionality and import them in main file cars.

Theory: A package is a collection of modules. It is a folder containing modules and \_\_init\_\_.py file to let python treat the folder as a package. Each module has methods for drive and start engine.

```
from cars.bmw import BMW
from cars.audi import Audi
from cars.nissan import Nissan

bmw_car = BMW(model="X5")
bmw_car.start_engine()
bmw_car.drive()
print()
audi_car = Audi(model="A4")
audi_car.start_engine()
audi_car.drive()
print()
nissan_car = Nissan(model="Altima")
nissan_car.start_engine()
nissan_car.drive()
```

# Output(Screenshot):-

```
ile-master/program53.py
BMW X5 engine started.
Driving the BMW X5.

Audi A4 engine started.
Driving the Audi A4.

Nissan Altima engine started.
Driving the Nissan Altima.
atharavpatil@Atharavs-MacBook-Air Lakshya46_23-23.
```

#### **Conclusion:**

Hence, creating a package containing modules for different car models, with each module containing methods for each car model.

Title: Write a program to implement Multithreading. Printing "Hello" with one thread & printing "Hi" with another thread.

Theory: Multithreading is used for multitasking as multiple processes are run in parallel at the same time. Each process is given a thread to run on and all the threads are joined together to create a main thread at the end of execution. Sleep is a function in time module which is used to suspend the execution of a thread for a specified number of

seconds.

```
from threading import Thread
from time import sleep
def hi():
        for i in range(10):
            print("Hi")
            sleep(0.5)

def hello():
        for i in range(10):
            print("Hello")
            sleep(0.5)

t1=Thread(target=hi)
t2=Thread(target=hello)
t1.start()
t2.start()
t1.join()
t2.join()
print("End of execution")
```

# **Output(Screenshot):**

```
Ηi
Hello
Ηi
Hello
Hello
Ηi
Hello
Ηi
Hello
Ηi
Hello
Ηi
Hello
Ηi
Ηi
Hello
Ηi
Hello
Ηi
Hello
End of execution
atharavpatil@Atharavs-MacBook-Air Lakshya46_23-27_Sem-I-_Pythonlabfile-master %
```

Conclusion: Hence, by using multithreading module in python to run multiple processes at once in parallel with each process getting their own threads to run on and joining them all at the end of execution of program. Also using sleep function from time module to let the processes on the threads run after a specified interval of time.

Title: Write a program to use 'weather API' and print temperature of any city, also print the sunrise and sunset times for the same humidity of that area.

### **Theory:**

Requests module is used to connect a website with our program and an API key is required to get information from any website. API key is used for authentication of a user for getting any information from a website. Datetime module is used to convert Unix Epoch time to IST time for user convenience.

```
api_key="8875b4b251a12102afaa386753424b54"
import requests
import datetime
city=input("Enter city: ")
response=requests.get(f"https://api.openweathermap.org/data/2.5/
weather?g={city}&APPID={api key}&units=Metric")
a=response.json()
print(a)
if 'message' in a:
    print("City not Found!")
else:
   print("\nCity:",city)
   print("Temperature:",a['main']['temp'],"C")
   print("Humidity:",a['main']['humidity'])
   print("Sunrise(IST):",datetime.datetime.fromtimestamp(a['sys']
['sunrise']))
    print("Sunset(IST):",datetime.datetime.fromtimestamp(a['sys']
['sunset']))
```

# **Output(Screenshot):**

```
Enter city: london

City: london
Temperature: 11.72 C
Humidity: 93
Sunrise(IST): 2023-12-25 13:35:20
Sunset(IST): 2023-12-25 21:25:15
```

### **Test Case: Any two (screenshot)**

```
Enter city: london

City: london
Temperature: 11.72 C
Humidity: 93
Sunrise(IST): 2023-12-25 13:35:20
Sunset(IST): 2023-12-25 21:25:15
```

```
Enter city: mumbai

City: mumbai

Temperature: 28.99 C

Humidity: 42

Sunrise(IST): 2023-12-25 07:08:45
```

### **Conclusion:**

Hence, using API of openweather to get weather details of user given city and printing the weather details with the help of requests module and date time module to convert Unix epoch time to IST time.

Title: Write a program to use the 'API' of crypto currency.

Theory: Requests module is used to connect a website with our program and an API key is required to get information from any website. API key is used for authentication of a user for getting any information from a website.

Code:

```
<mark>api_id=</mark>"CG-YY7sXzq1xmN5cijfXUY5kFb4"
import requests
while True:
    coin=input("Enter cryptocoin: ")
    response = requests.get(f"https://api.coingecko.com/api/v3/
simple/price?ids={coin}
&vs currencies=usd,inr&x_cg_demo_api_key={api_id}")
    a=response.json()
    if coin in a:
        print(a)
        print("\nCrypto:",coin)
        print("Price:",a[coin]['usd'],"USD")
print("Price:",a[coin]['inr'],"INR")
    else:
        print("Invalid cryptocoin!")
    b=input("Want to see more cryptocoins?(y/n): ")
    if b.lower() == "n":
        break
coin=input("Enter cryptocoin: ")
```

# Output(Screenshot):

```
Enter cryptocoin: ethereum

Crypto: ethereum

Price: 2271.57 USD

Price: 188933 INR

Want to see more cryptocoins?(y/n): y

Enter cryptocoin: abc

Invalid cryptocoin!

Want to see more cryptocoins?(y/n): n
```

# **Test Case: Any two (screenshot)**

```
Enter cryptocoin: bitcoin

Crypto: bitcoin

Price: 43481 USD

Price: 3616407 INR

Want to see more cryptocoins?(y/n): n
```

```
Enter cryptocoin: ethereum

Crypto: ethereum

Price: 2271.57 USD

Price: 188933 INR

Want to see more cryptocoins?(y/n): y
Enter cryptocoin: abc
Invalid cryptocoin!

Want to see more cryptocoins?(y/n): n
```

### **Conclusion:**

Hence, using API of CoinGecko to get price of cryptocurrency given by the user and printing INR and USD price and asking for more crypto till the user chooses the option to terminate the program using while loop.
